Executive Summary

The Goose Point/Point Platte Marsh Creation Project (PO-33) is an ecosystem restoration effort approved for feasibility study, engineering and design under the Coastal Wetlands Planning, Protection, and Restoration Act (CWPPRA). The cost of the project will be shared by the Louisiana Department of Natural Resources (LDNR) and the United States Fish and Wildlife Services (USFWS). The project will entail creation of 440 acres of marsh within the boundaries of the Big Branch Marsh National Wildlife Refuge and the St. Tammany State Wildlife Refuge using material dredged from borrow areas in Lake Pontchartrain. Borrowed sediment would be placed in cells within interior marsh ponds. The cells would be formed by constructing earthen dikes around the boundaries of the ponds. An additional 120 acres of degraded marsh would be nourished with material dredged from the proposed borrow areas in the lake.

During the month of January 2006, PBS&J surveyed baseline stations to provide reference points to established benchmarks at Goose point, and conducted geophysical surveys over two proposed borrow areas along the northern shore of Lake Pontchartrain. Surveys conducted under this work authorization were financed and reviewed by LDNR. A total of seven baseline stations, named GP (Goose Point) 1 through 7, were selected to be set along the northern shore of Lake Pontchartrain within the boundaries of Big Branch Marsh National Wildlife Refuge (BBMNWR). Geophysical survey instrumentation included a magnetometer, a recording fathometer, a CHIRP sub-bottom profiler and side-scan sonar. Survey coverage included 6900 acres of lake bottom and totaled 84 miles of survey transects.

1.0 INTRODUCTION

During the month of January 2006, PBS&J surveyed baseline stations to provide reference points to established benchmarks at Goose point, and conducted a hydrographic and geophysical survey over two proposed borrow areas along the northern shore of Lake Pontchartrain (Figure 1). The primary purpose of the survey was to gather sufficient information to assist the Louisiana Department of Natural Resources (LDNR) with their evaluation of the proposed borrow areas as sediment sources for a marsh creation project and to provide survey control points for construction activities. The project site is located in St. Tammany Parish, Louisiana, along the north shore of Lake Pontchartrain, within the boundaries of the Big Branch Marsh National Wildlife Refuge and the St. Tammany State Wildlife Refuge. Three types of survey data were required as part of this study: bathymetric, magnetic and sub-bottom profiling or seismic. The geophysical surveys covered 6900 acres of lake bottom and totaled 84 miles of survey transects. Side-scan sonar, although not part of the scope of services, was run over 915 acres (23 transect miles) of the survey areas at no expense to LDNR in order to aid sub-bottom interpretation by characterization of lake bed sediments. All but 47 acres (1 mile) of the side-scan data was acquired in the Goose Point survey area. This report provides the results of the land survey and bathymetric, magnetic and seismic surveys, along with the geologic interpretation of seismic survey results.

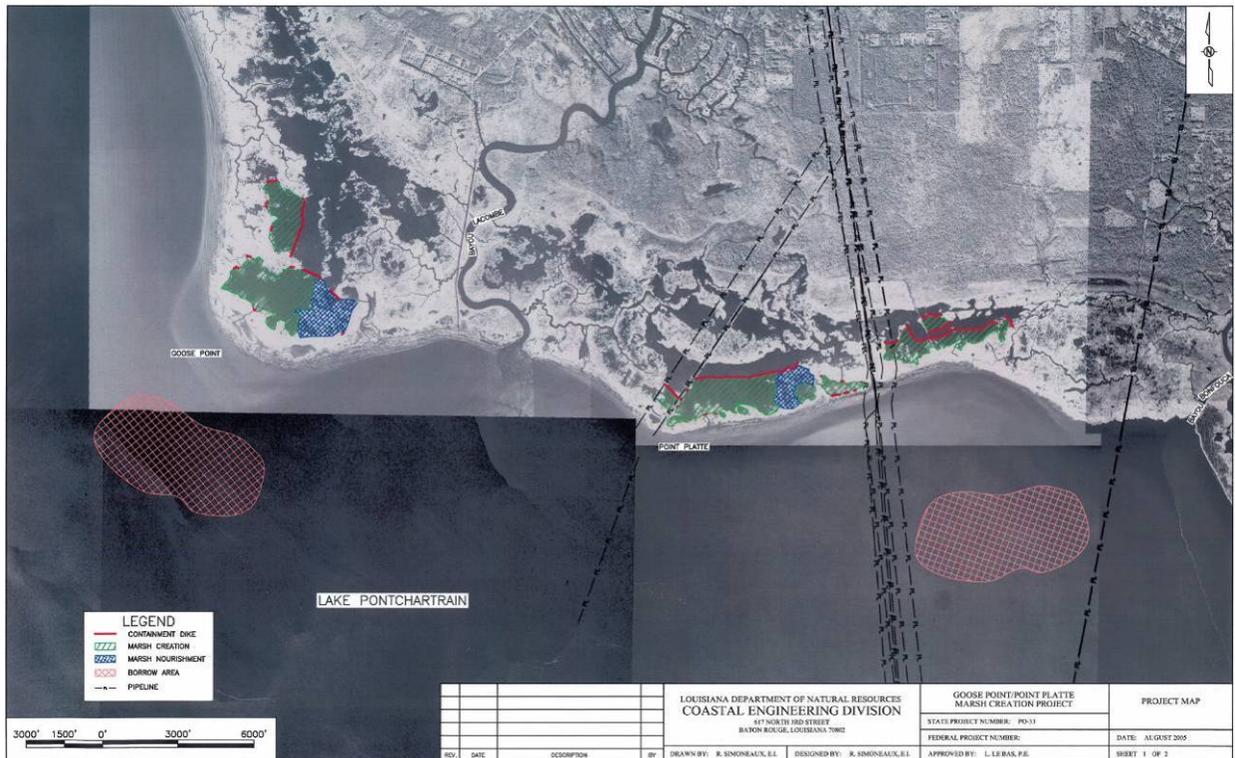

Figure 1: Proposed Borrow and Marsh Creation Areas (courtesy of LDNR)

Approximately 440 acres of marsh will be created by dredging material from Lake Pontchartrain and placing it in cells within interior marsh ponds (see Figure 1). The cells will be formed by constructing

earthen dikes around the boundaries of the ponds. In addition, approximately 120 acres of degraded marsh will be nourished with dredged material from the proposed borrow areas in the lake. The surveys encompassed both proposed borrow sites and surrounding areas of lake bottom (Figure 2). Lake bed elevations from the bathymetric portion of the survey ranged from -14.5 feet (ft) to -3.5 ft (North American Vertical Datum [NAVD] 1988).

2.0 SURVEY METHODS

2.1 BASE LINE STATION SURVEY

Pursuant to the Scope of Services to be provided by the surveyor, a total of seven baseline stations, named GP (Goose Point) 1 through 7, were selected to be set along the north shore of Lake Pontchartrain within the boundaries of Big Branch Marsh National Wildlife Refuge (BBMNWR). These points were selected to minimize the number of points of intersection (PI's) per requirements in said Scope of Services. Following recovery of the two primary control points SM-01 and SM-02, alternate means of accessing the selected points were investigated. Aluminum caps to be placed on top of the iron rods monumenting the control stations were stamped and center punched. Due to the marshy nature of the terrain and the absence of road access to the lake, it was determined that with the exception of GP-4, which is located at the southerly end of LA 434 (Lake Road), the only means of reaching the control point locations was by boat. Windy conditions on the lake prevented the use of a small shallow-draft boat needed to access the points on the bank until Tuesday the 10th of January, 2006. On Tuesday, 3-foot long ¾-inch iron rods were set with a stamped cap at stations GP-2 thru GP-7 and the top of the tide gauge used for the hydrographic survey was also shot with GPS (RTK with the base set on SM-01). As the control points were set, coordinates were obtained using RTK. The only station not located from SM-01 was GP-1 which required setting the RTK base on SM-02 to maximize radio reception. A closer boat launching location to GP-1 was found along Carr Drive off of LA Hwy. 11 in Slidell. The crew schedule was hampered by the BBMNWR regulations during duck hunting season which only allow access on Monday, Tuesday and Friday. The field crew returned to the site on Monday the 16th of January, 2006 and completed the baseline portion of the job. The data collector was downloaded and the coordinates from all the control stations were retrieved referenced to NAD83 Louisiana State Plane Grid, South Louisiana Zone (1702) and NAVD88 vertical datums. Monument recovery sketches are being prepared showing monument locations spotted on USGS quad-sheets and containing x, y and z coordinates as well as WGS84 latitude and longitude.

2.2 GEOPHYSICAL SURVEYS

Geophysical equipment included: an Odom Hydrotrac echo sounder with a 9-degree, 200-kHz transducer; a TSS DMS-05 heave compensator; a Valeport 740 automated tide meter; an Edgetech SB-424 CHIRP sub-bottom towfish; an Edgetech Full Spectrum Sub-Bottom (FSSB) topside signal processor; a Geometrics G882 magnetometer; an Edgetech DF1000 500-kHz side-scan sonar towfish (outside of scope; partial coverage only); and two CODA Technologies data acquisition systems running

CODA *Geosurvey* software. Horizontal positioning of the survey boat was accomplished using Hydropro 2.1 navigation software and a Trimble Ag132 global positioning system (GPS) equipped with a US Coast Guard differential correction receiver. The navigation software was configured to log data from the echo sounder, magnetometer and GPS simultaneously. GPS events were recorded at 1-second intervals. The survey was conducted at an average speed of 4.4 knots (5.1 miles per hour), resulting in an average in-line distance between logged positions of 7.45 ft (2.27 m). GPS positions were integrated into echo sounder analogue charts, as well as sub-bottom and sonar imagery, as each was recorded.

Survey lines were based on coordinates provided in Table 2, Appendix B in the scope of services. The pre-survey plot of planned survey lines is reproduced from the scope of services below as Figure 2. Survey was conducted along transects spaced at 1000-ft (305-m) intervals and oriented orthogonal to the shoreline. Transect spacing across the proposed borrow areas was reduced to 500 ft (152 m). The combined length of all 49 survey lines totaled 84 miles. Shallow portions of lines extending to the shoreline were excluded from the survey. Three tie lines were surveyed across each borrow area in a direction orthogonal to the primary transects. The main purpose of the tie lines was to locate pipelines with the magnetometer.

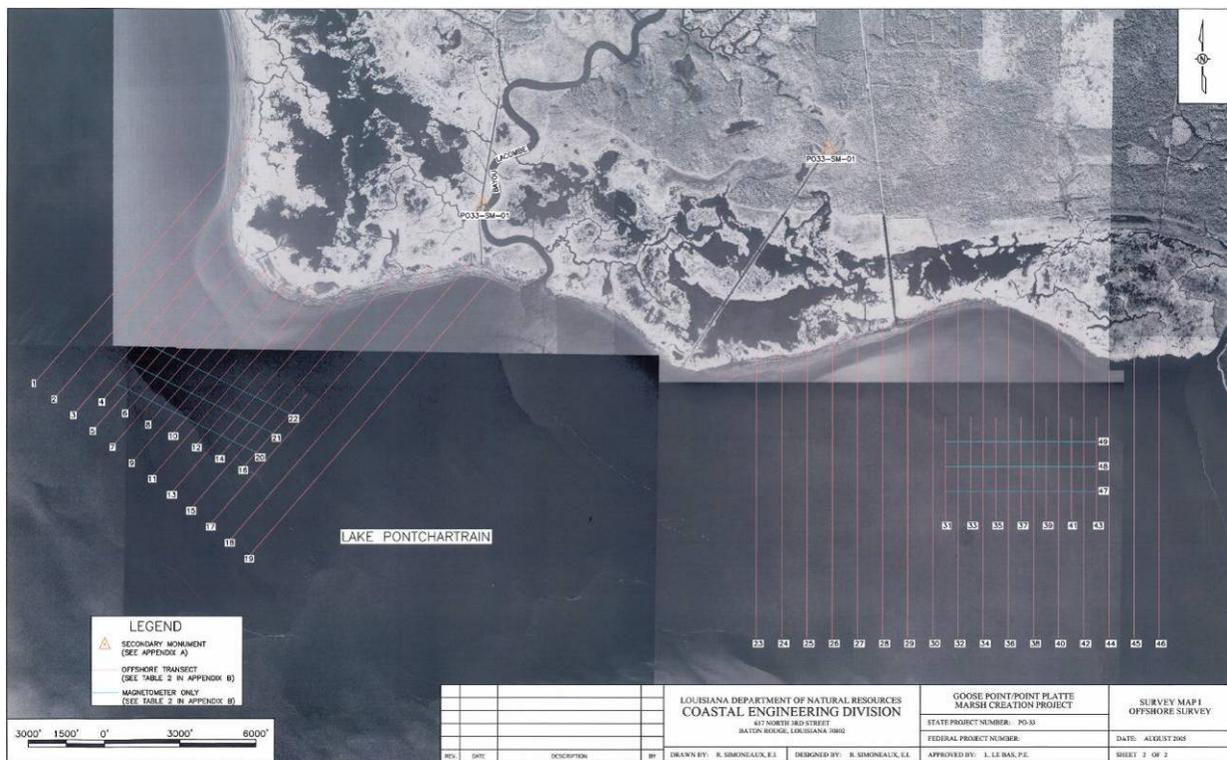

Figure 2: Pre-survey Plot of Hydrographic/Geophysical Transects (courtesy of LDNR).

Fieldwork took place from January 4-12, 2006. All geophysical data were acquired simultaneously from a 20-foot aluminum workboat, MV *PeeWee McKinney*. Mobilization of the survey boat, equipment and crew to Lake Pontchartrain occurred on January 4. Geophysical equipment was assembled on the boat on

January 5. Figure 3 illustrates the horizontal offset of sensors on the survey vessel. Equipment was tested in protected waters and an automated tide gauge was installed on January 6. Strong winds from a cold front prevented data collection on either January 5 or 6. Data collection occurred on January 7, 9, 10 and 11. No data was logged on January 8 due to a combination of equipment malfunctions and high wind in the afternoon. Portions of the survey area near shore could not be accessed by the survey vessel, as water depths diminish rapidly forming a broad gently sloping shoal along the northern shore of the lake in this area (Figure 4).

2.2.1 Bathymetry Survey

Bathymetric data were acquired using an Odom Hydrotrac echo sounder (Figure 5) with a 200-kHz 9-degree beam transducer. The echo sounder transducer was located 1.3 ft (0.4 m) beneath the surface, 3.6 ft (1.1 m) to the starboard side of and 1.6 ft (0.5 m) forward of the GPS antenna. The navigation software calculated and recorded position estimates for the echo sounder transducer in real-time. Water depth was recorded approximately 10 times per second, so the distance between consecutive soundings averaged 0.7 ft (0.2 m).

Water depths were compensated for vertical wave motion (heave) of the transducer in real-time using a TSS DMS-05 Motion Sensor (Figure 5). The motion sensor was mounted on the floor of the survey vessel immediately inboard of the echo sounder transducer. Heave data were imported to the echo sounder through a serial data port. Heave compensated depths were then exported from the echo sounder through another serial port to the navigation computer for data storage.

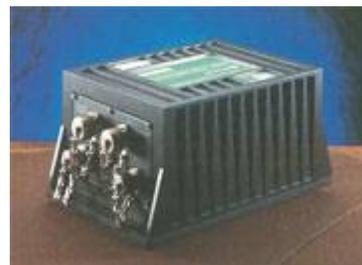

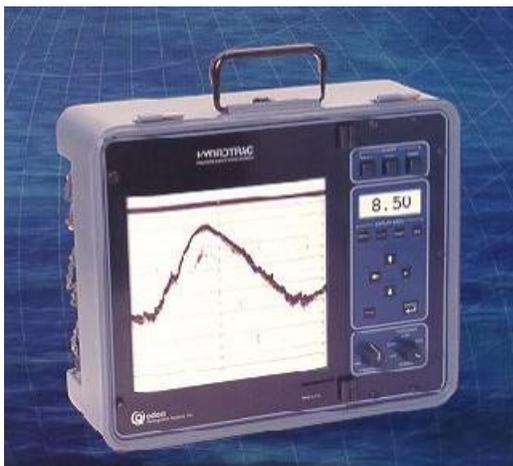

Figure 5: Odom Echo Sounder and TSS DMS-05 Heave Compensator

The echo sounder was calibrated (bar checked) at the start and end of each survey day using a flat steel bar suspended horizontally between chains at measured depths directly beneath the transducer. Any variation in calibration noted at the end of the survey day would be incrementally corrected for all water depths recorded since the time of the previous bar check. Bar checks were conducted in protected waters just inside the mouth of Bayou Lacombe. Tidal data was collected at 10-minute intervals throughout each survey day using a Valeport 740 tide gauge. The tide gauge (Figure 6) was mounted on a red navigation marker in Lake Pontchartrain slightly off the mouth of Bayou Lacombe.

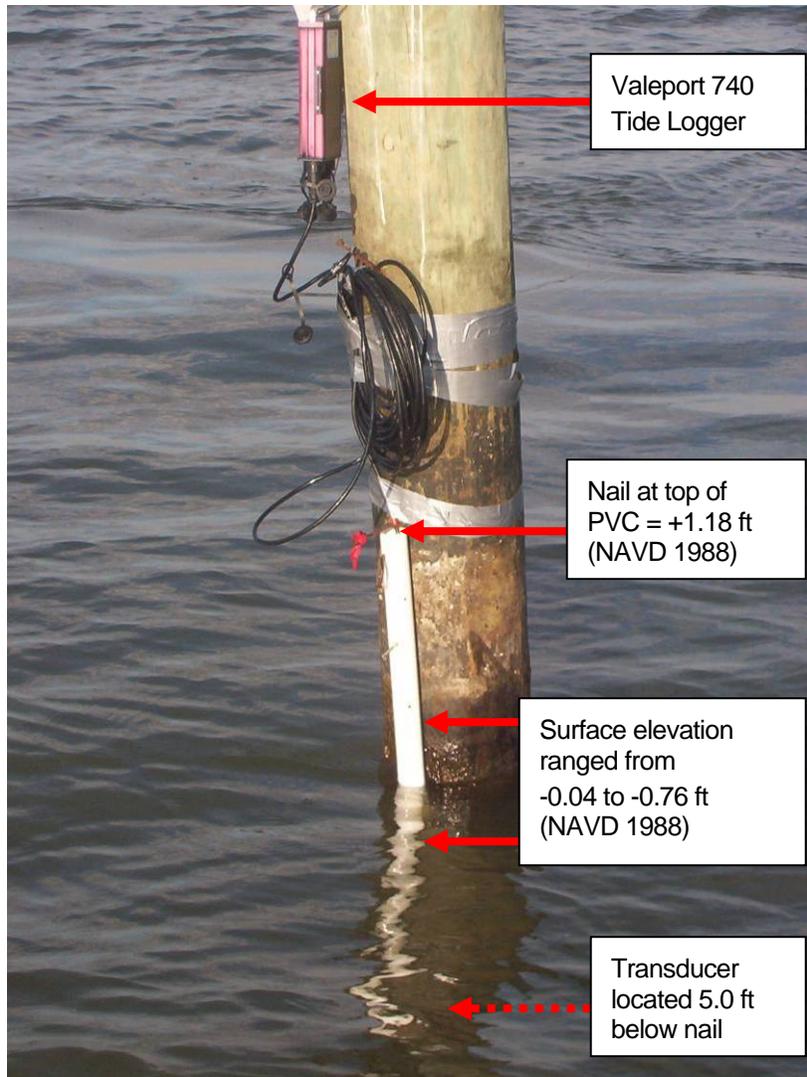

Figure 6: Tide Gauge Established for Project

Water depths were edited to remove noise spikes and reduced to elevations based on the NAVD 1988 datum using *HydroPro NavEdit*. Vessel squat corrections were calculated based on vessel speed using a spreadsheet. Squat corrected elevations were next subjected to two iterations of a shoal bias filter based on a 3-point running comparison to identify and remove the low lying center points from each set of 3 adjacent elevations. This process slightly smoothes the data with a bias toward retaining the highest

elevations. Next, the shoal-biased elevations were smoothed slightly using a 5-point running average. Finally, the dataset was thinned to a sample rate of approximately one elevation per half second.

Elevation contours were prepared using Bentley's GeoPak digital terrain modeling software. This process involved creation of a triangle surface model. A square lattice was produced on a 20 x 20 meter grid from the triangle surface. The elevation of each lattice intersection was assigned through linear triangulation along the sides of the nearest triangle in the model. The grid interval was chosen to provide some smoothing of the contours for the sake of report presentation only. Contours were also subjected to "B Spline" smoothing as they were drawn by GeoPak.

2.2.2 Magnetometer Survey

A magnetometer survey was conducted using a Geometrics G-882 cesium vapor towfish (Figure 7). This sensor was towed at the surface 48.9 ft (14.9 m) directly aft of the GPS antenna. Total-field magnetic readings were recorded in nanoteslas (or gammas) at 1-second intervals. Magnetometer data from the combined survey lines were diurnally corrected using a mathematical algorithm, then reduced to relative values centered on zero, and contoured while in the field in order to locate anomalies requiring additional survey. All magnetic anomalies were boxed in by subsequent survey to rule out their association with pipelines.

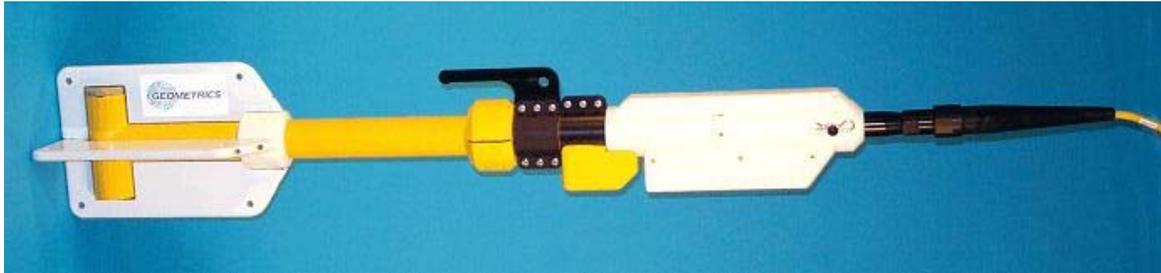

Figure 7: Geometrics G-882 Magnetometer

2.2.3 Sub-Bottom Profiler Survey

The sub-bottom profiler geophysical survey was conducted using an Edgetech SB-424 CHIRP towfish (Figure 8) operating with a bandwidth of 4-24 kHz and a pulse repetition rate of 250 milliseconds (ms). The 2,000-watt amplifier was operated at 75-90 percent power. Published specifications for the SB-424 towfish claim 1.6-inch (4-cm) vertical resolution for this system, as configured, and a beam width of 16 degrees.

Figure 8: Edgetech SB-424 CHIRP Seismic Profiler

The raw CHIRP data was recorded by the Coda *GeoSurvey* acquisition system directly to DVD disks. The navigation software calculated and recorded position estimates for the SB-424 towfish in real-time and relayed those positions to the sub-bottom acquisition computer for integration into the digital seismic record. The SB-424 was towed 3.6 ft (1.1 m) to port of and 3.9 ft (1.2 m) forward of the GPS antenna.

2.2.4 Side-Scan Sonar Survey

An Edgetech DF1000 side-scan sonar was towed during a portion of the survey, although it was not a required element of the project. This data was intended to compliment that recorded by the sub-bottom profiler by providing information concerning surface sediments. Unfortunately, we were forced to abandon the effort in order to borrow a computer power supply from the sonar system in order to repair the FSSB computer, which was essential for sub-bottom seismic acquisition. The sonar, while it was operated, recorded a continuous seabed image covering a swath of 164 ft (50 m) on each side of the towfish path. Approximately 23 line miles of sonar profile data were collected. The raw sonar data was recorded by the Coda *GeoSurvey* acquisition system directly to DVD disks. The navigation software calculated and recorded position estimates for the sonar towfish in real-time and relayed those positions to the sonar acquisition computer for integration into the digital sonar record. The side-scan sonar towfish was deployed at a depth of approximately 2 ft (0.6 m), 3.6 ft (1.1 m) to the starboard side of and 11.8 ft (3.6 m) forward of the GPS antenna. Upon completion of the sonar data acquisition, a mosaic image was created, which was converted to a geotiff format with a resolution of 10 pixels per meter and imported into Microstation CADD software.

2.3 GEOPHYSICAL DATA PROCESSING

Data captured by the topside recorder was stored in CODA format files and subsequently converted to SEG-Y format. Data processing was performed by loading the SEG-Y files for each profile into a viewer program for initial review of the section lines, individual traces and digital data point values. Because the analog to digital conversion of the reflection signals was performed using a routine that rectified the chirp

data, phase information was not retained in the reflection trace records. Some recording of negative values was noted in the reflection maxima for the water bottom reflector, and this was determined to be an artifact of the data transformation and recording process.

For interpretation, a number of data processing steps were performed to improve the resolution of the profiles. Because the reflection signal was rectified as noted above, traditional seismic data processing techniques such as deconvolution were not performed. Additional gain adjustment was performed using an automatic gain function with a 5 ms averaging window. The color assignments for the reflection profile images were also adjusted to help suppress the display of noise in the sections. Finally, stacking was performed by taking four neighboring profiles for each line trace and summing the weighted values at each time interval to enhance signals from laterally continuous reflectors that are typically associated with geologic features such as bedding or erosional contacts. While this step also increased the strength of reflection multiples from the water-sediment interface, the improved signal to noise ratio in the early portion of the traces aided geologic interpretation of the shallow data.

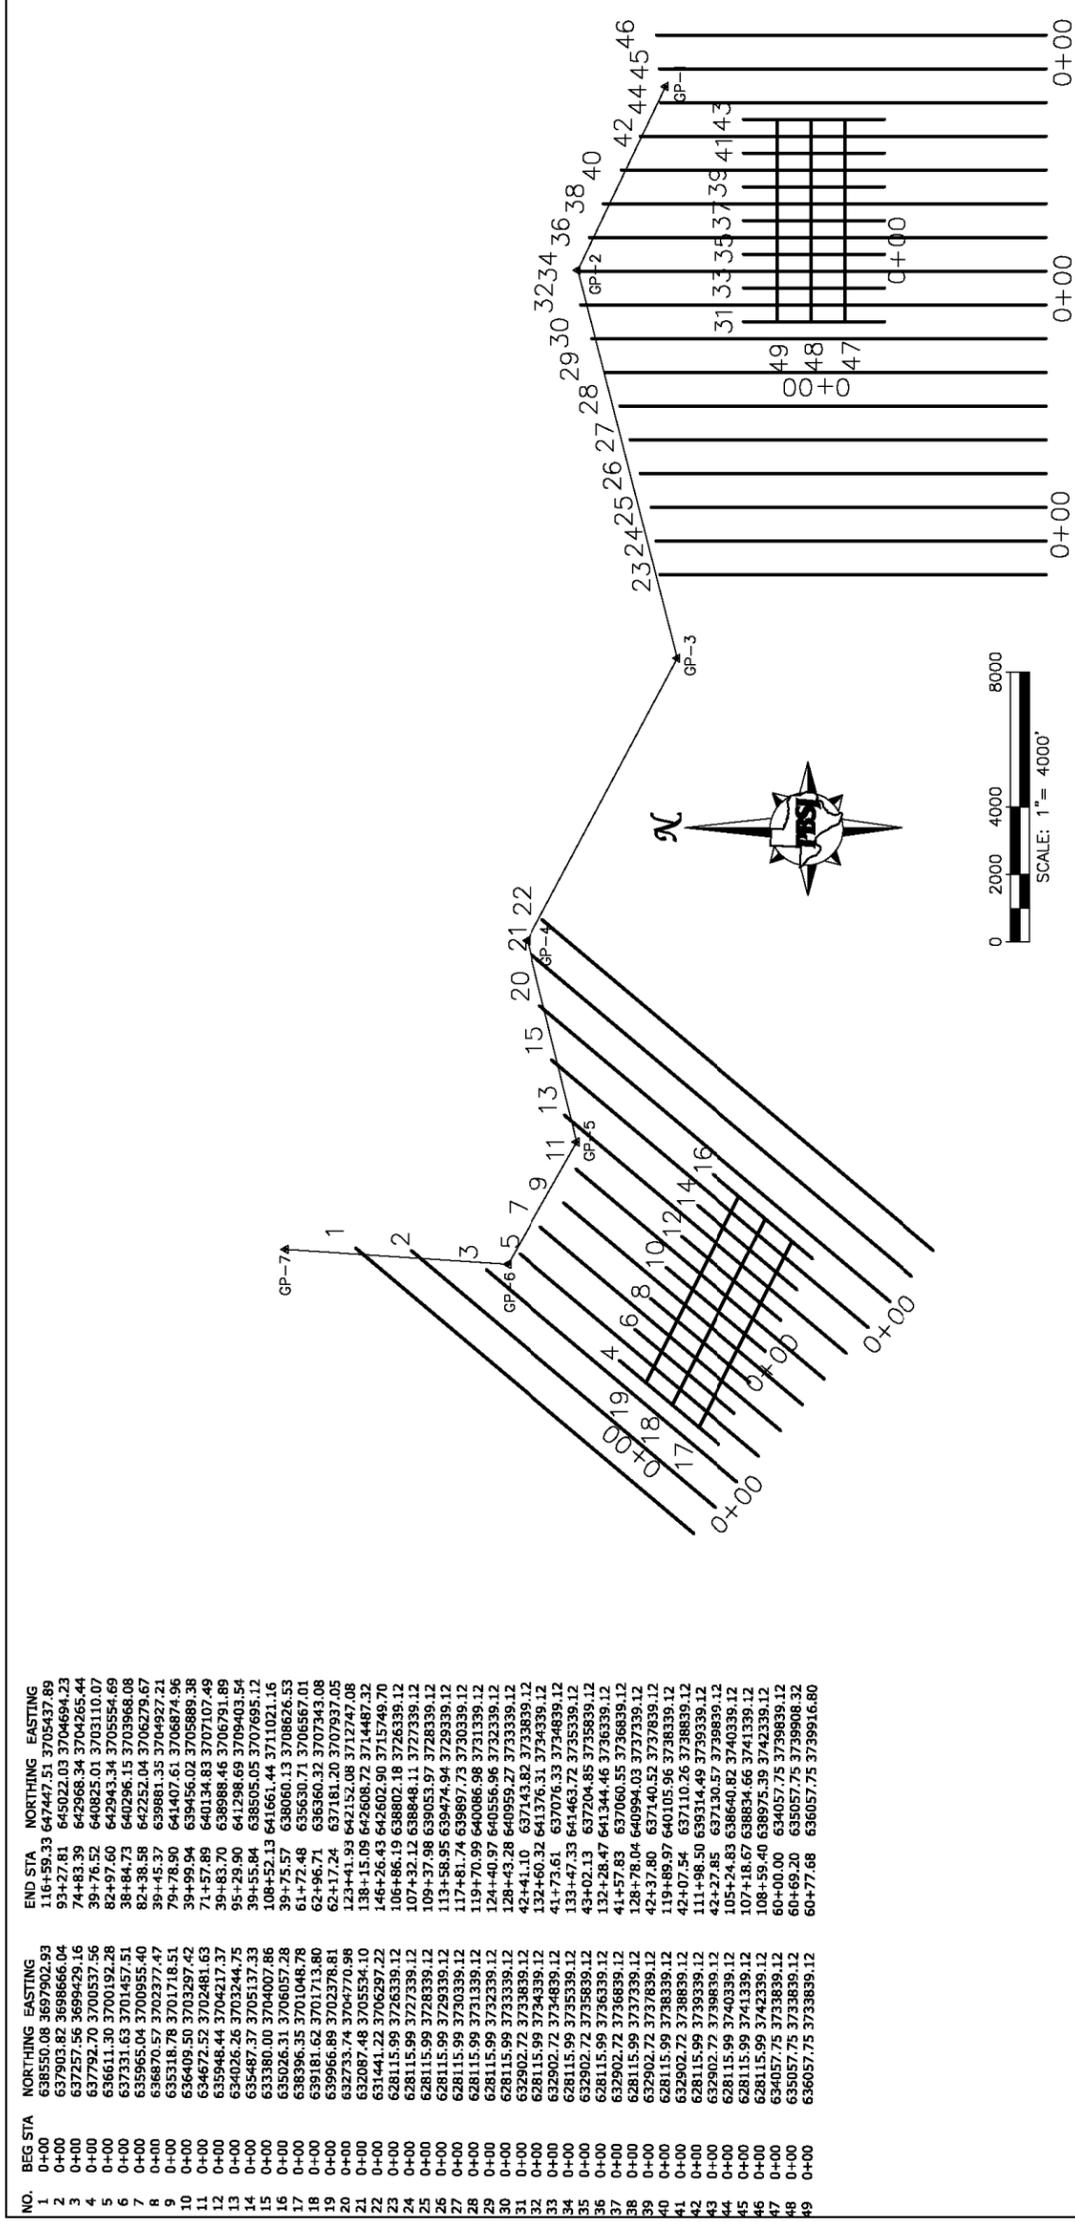

3.0 RESULTS AND DISCUSSION

3.1 BASELINE LOCATIONS

The recovery of primary control points, acquisition of coordinates and baseline survey completion and monument placement were completed within the requirements provided in the scope of services for these project elements. Documentation and reference to NAD83 Louisiana State Plane Grid, South Louisiana Zone (1702) and NAVD88 vertical data were also completed. The location and reference elevations should provide sufficient survey control for project construction, verification and monitoring. The baseline survey map is provided as Figure 9.

3.2 BATHYMETRY

Bathymetry of the borrow areas was collected, corrected and used to prepare contour maps of the borrow areas for the project. The water depth information provided is suitable for determining borrow material and dredge operation volumes. While some data indicate the presence of soft bottom conditions, the combination of bathymetric and sub-bottom profiler data indicate that there is not sufficient loose, partially suspended material at the water bottom to interfere with the data collected. Figures 10 and 11 show the contoured bathymetry of the borrow areas. Bathymetric cross-sections are provided in Appendix A.

3.3 MAGNETIC ANOMALIES

The magnetometer survey results are shown on Figures 12 and 13 as magnetic contours. The 5-nanotesla contours are color coded to indicate polarity of anomalies relative to the local amplitude of earth's magnetic field. Shades of red indicate positive polarity, and shades of blue indicate negative polarity. Contours were drawn based on linear interpolation between adjacent transects, thus anomaly sizes appear exaggerated in the cross-line direction. Anomaly amplitudes and dimensions are accurately represented within each transect where they occur. The magnetometer survey data confirmed the presence and orientation of documented pipelines in the borrow areas. Additional data lines were surveyed across suspected pipelines in order to determine their approximate lateral limits. The locations of all magnetometer survey transects are included in Figures 12 and 13. A number of smaller anomalies were detected that were of very limited lateral extent and exhibited a wide range of field strength values. These anomalies were evaluated by collecting additional data in a closed loop around each to confirm their limited lateral extent and lack of association with pipelines.

3.4 GEOLOGIC INTERPRETATION

Seismic profiles for all of the long primary lines are illustrated in their respective geographic orientations in Figures 14 and 15. A complete set of stacked analogue records for all 49 survey lines also is provided as Appendix B. The location and orientation of the profiles were compared to existing geologic and stratigraphic information, including the stratigraphic section and elevation of the top of the Pleistocene sediments summarized in McCarty and Penland, 2002 (Figures 16 and 17).

3.4.1 Bottom Reflector Signatures, Sediment Types and Shallow Subsurface Conditions

The characteristics of the sediment-water interface reflection signal were compared to available side-scan sonar imagery of the lake bottom and bathymetry data collected during the survey. The lateral distribution of lake bed sediment units, relict channels and pipeline areas are illustrated in Figures 18 and 19. These data were used to derive the distribution of sediment types for the lake bottom in the survey areas. In general, active oyster mounds and areas of shell rich sediment occur along slight bathymetric highs, and very soft, fine-grained sediment with high water content is present at the lake bottom in the low areas.

It was noted during the initial review of sub-bottom profiles that many included a bottom reflector signal that was influenced by the reflection coefficient and bottom roughness, although the data format and range of values did not allow quantitative evaluation of the reflection coefficient. In general, oyster mounds and shelly sediment at the sediment water interface typically had significant small scale variations in apparent depth, and were characterized by a very high amplitude reflection. Areas with fine-grained sediment at the sediment-water interface typically had much lower amplitude for the reflection from the interface, and lower amplitude reflections and reflection multiples were observed in the later time periods of these traces. These characteristics are attributed to the lower acoustic impedance and greater attenuation of the signal in uncompacted fine-grained sediments of recent lake bottom deposits.

Beneath the sediment-water interface reflection, the profiles often contained a record interval ranging from a fraction of a millisecond to two milliseconds with a number of relatively high amplitude peaks. Lateral continuity or stratigraphic correlation of peaks in this zone was generally not evident. This reflection pattern was interpreted to be produced by fine grained sediments that contained relict oyster mounds beneath the surface, and individual shells and high gas content that contributed to the high amplitude, laterally discontinuous peaks in this zone. Below the shallow zone of loose sediment, shells and oyster mounds, a zone of low signal return was noted that typically had a time length of 2 milliseconds in the reflection profile. Beneath this zone, most reflections were determined either to be multiples of the water-sediment interface or reflections indicating a high noise to signal ratio, reflecting the higher gain used for collection of later time periods of each trace.

3.4.2 Geologic Interpretation of Profiles

A series of profiles across the study area were evaluated for geologic interpretation, and reflectors were identified that potentially indicate significant geologic boundaries. At the Goose Point segment of the study area, geologic interpretations are provided for profiles 2, 9 and 19 (Plate 1). At the Point Platte survey area, interpretations are provided for profiles 24, 27 and 38 (Plate 2).

Figure 18: Sediment Distribution and Available Side-Scan Sonar Imagery at Goose Point

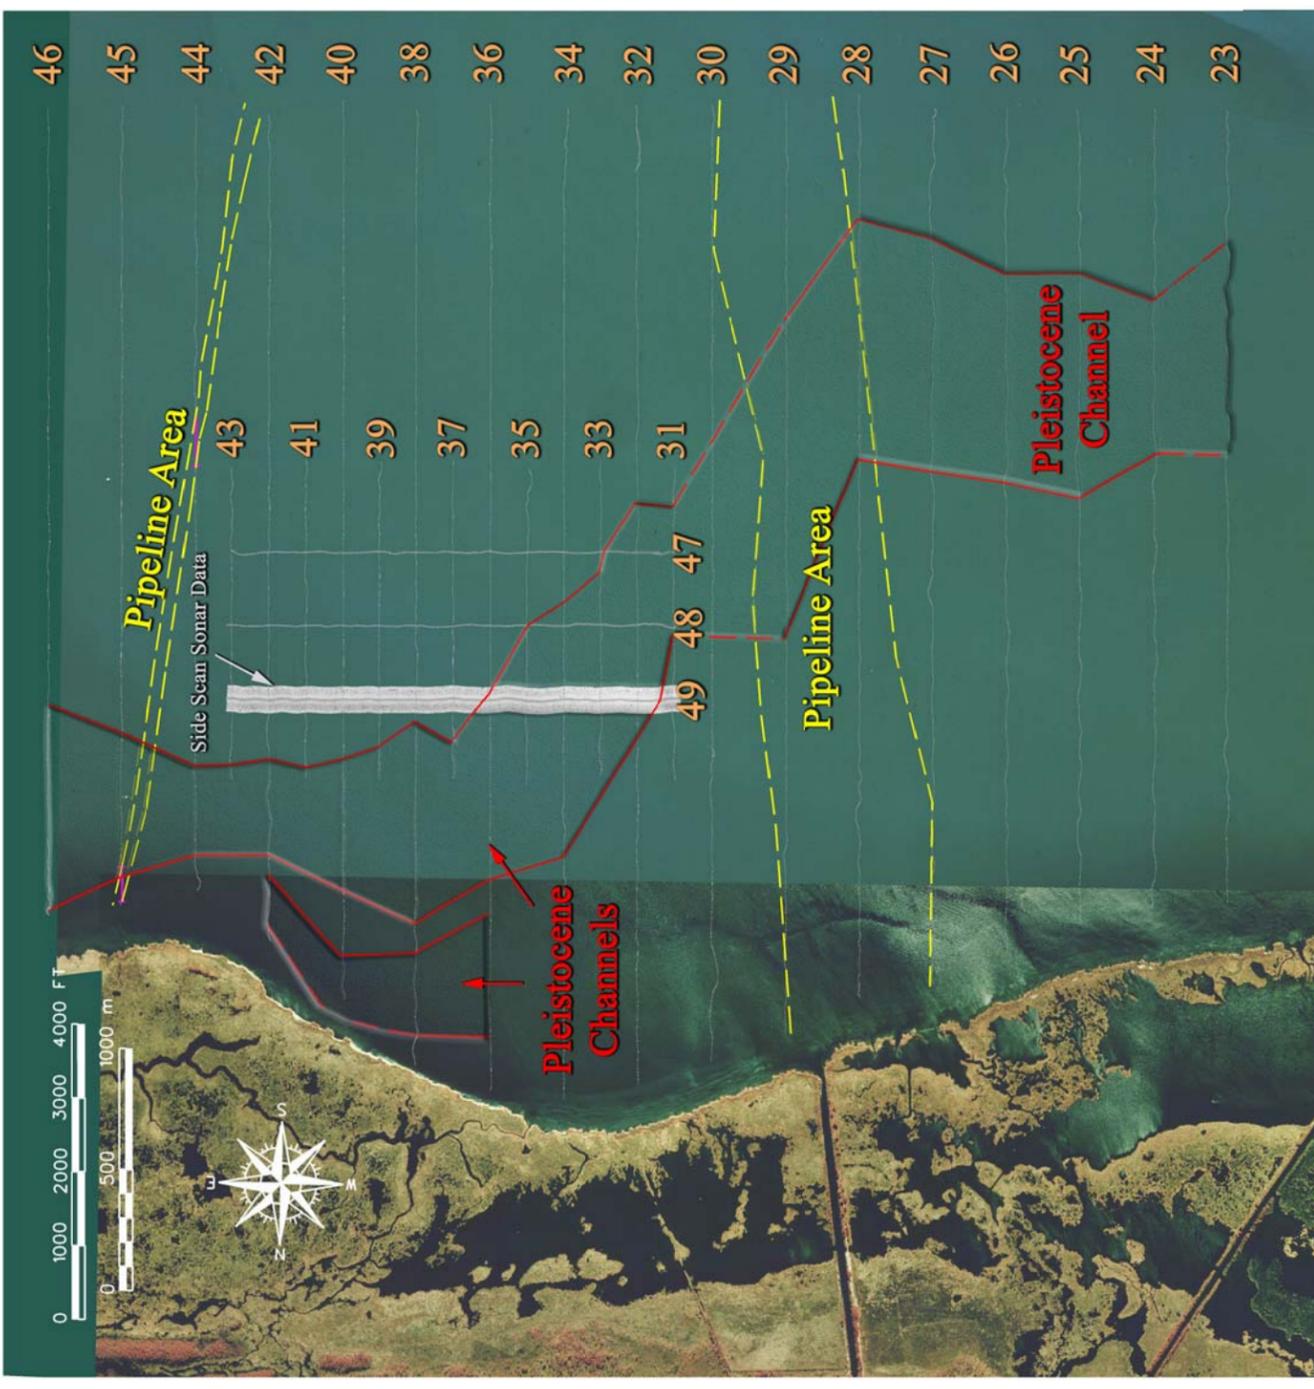

Figure 19: Relict Channels, Pipeline Areas, and Available Side-Scan Sonar Imagery at Point Platte

3.4.2.1 Goose Point Survey Area

Along profile 2 (Plate 1), the lake bottom has a high slope near the lake shore, and is less steep to the southwest. A relatively strong reflector is present at approximately 4 milliseconds near the shoreline, and this reflector is interpreted to be the contact between Recent and Pleistocene sediments. The erosional nature of the contact is shown by the vertical relief on this surface, which rises in depth and then slopes downward to the southwest. Nearly halfway along the profile, this reflector overlaps with the first multiple of the sediment water interface, and cannot be identified in the reflection traces recorded further along the profile. A number of internal reflectors are also noted in the overlying sediment. These reflections probably were produced by lithologic contacts between the modern lacustrine sediments and underlying beach and estuarine deposits. An additional segment of a reflector that may have been produced by the Pleistocene—Recent contact was also identified below the first multiple in the southwestern portion of the profile.

Very shallow water is present along the shoreward portion of profile 9 (Plate 1), with a pronounced break in slope and increase in water depth approximately one quarter of the profile length from the shoreline end of the section. This bathymetric relief may be a geomorphic expression of the Goose Point Fault, a component of the Baton Rouge – Denham Springs Fault System, which generally trends sub parallel to the northern shore of Lake Pontchartrain. Fault locations shown on the interpreted profiles are based on regional data (McCarty and Penland, 2002), and were refined to match potential offsets identified on the water bottom and subsurface reflectors. The sediment-water interface reflection has relatively high amplitude and low relief in this area. This may be caused by higher sand content of sediment at the lake bottom. A shallow reflector appears to drape across the subsurface beneath the escarpment. This might indicate the presence of syndepositional faulting, with the youngest section increasing in thickness on the downthrown fault block. Unfortunately, reflections beneath the escarpment are confounded by the first multiple of the sediment water interface. From this area of the profile to the southwestern end, a reflection was identified as the potential Recent Pleistocene unconformity, generally sloping very gently to the southwest.

Profile 19 (Plate 1) does not exhibit the break in slope observed in Profile 9. The slope of the Lake Bottom gradually decreases along the profile and crosses a slight bathymetric high near its southwestern end. Surficial sediment characterized by abundant discontinuous reflections thickens to the southwest as water depth increases and then appears to decrease in thickness further along the profile. Along this portion of the profile, the initial reflection has low amplitude typical of very soft, fine grained sediment. A zone of strong reflections, present just beneath the sediment-water interface, might be caused by a relict oyster mound or reef that is now being buried by ongoing deposition. The reflection interpreted as the Pleistocene – Recent contact varies in depth along the profile, indicating the erosional topography of the surface. The reflection for this contact is not discernable in the profile beneath the relict oyster mound/shell layer, but is clearly present along the southwestern end of the section. Possible displacement along the Goose Point Fault is present near the northeastern end of the profile, and the boundary decreases and increases along the profile, indicating a very gentle overall slope on the surface in this area.

3.4.2.2 Point Platte Survey Area

Profile 24 (Plate 2), located near the western end of the Point Platte section of the survey area, shows a complex interaction of reflectors and data artifacts. Shallow water near the lake shoreline drops along an escarpment with approximately 7 feet of relief, and the lake bottom slopes very gently along the rest of the profile. The reflection from the sediment water interface has a high amplitude and very little relief, indicating possibly sandy sediments in the very shallow water segment of this profile. The first multiple of the sediment water interface has double the apparent relief of the escarpment, and makes identification of geologic markers problematic in this area. The top of the Pleistocene is indicated further along this profile by the reflection at approximately 6 ms. This surface has some relief and dips suddenly in mid-profile, possibly reflecting offset along the Goose Point Fault. Further to the south, the reflection is truncated by the margin of a channel cut, which extends across most of the southern portion of the profile, and the southern margin of the channel is indicated where the depth to the top of the Pleistocene decreases towards the south. Internal reflections in the overlying sediment are less numerous than observed at the Goose Point sections, possibly indicating more consistent grain size distribution in the upper section in this area. Profile 27 (Plate 2) presents similar reflection patterns as profile 24, with a pronounced near shore escarpment, and potential relief and offset on the Pleistocene – Recent contact. In addition, the channel cut and fill within the Pleistocene sequence observed at shallow depths in profiles to the west of this location is more deeply incised.

Profile 38 (Plate 2) is typical of the profiles along the eastern portion of the Point Platte survey area. The near shore segment of the profile is characterized by a less pronounced break in slope and shoaling near the end of the profile, and high amplitude reflections and a smooth topography indicate sandy sediments along the water bottom to a water depth of approximately 7 feet. Underlying the northern portion of the profile, the channel cut and fill sequence is present at a location further north than observed in the profiles west of this location. The series of reflectors exhibit strong relief and cross-cutting relationships provided the basis for interpreting this feature a channel cut and fill sequence that was then traced westward across the study area. Based on existing stratigraphic data, the fill material is interpreted as being of Pleistocene age, with a veneer of Recent lacustrine and estuarine sediments overlying this sequence in the eastern portion of the study area. South of the apparent channel margin, a reflector interpreted as the top of the Pleistocene is present, and a discontinuity of this surface further south may reflect offset on the Goose Creek Fault. The expected depth of the unconformity is obscured by the first multiple of the water sediment interface along the rest of the profile. Internal reflectors within the recent sediments indicate possible layering and grain size variation in this portion of the section. Relief on the water bottom and subsurface reflectors indicating potential offset along the Goose Creek Fault were not observed on this profile, and the fault location shown on the profile is based on fault trends provided in previously published studies. The map view of the survey area in Figure 19 shows the inferred extent of the buried channel and distribution of oyster mound and fine-grained sediments at the sediment-water interface in plan view.

4.0 CONCLUSIONS AND RECOMMENDATIONS

Baseline survey, bathymetry, magnetic anomaly and sub-bottom profile data were collected to support the dredging and construction activities for the Goose Point marsh restoration feature. Each of the data types collected was sufficient to meet the relevant specifications and intended uses of the data. Documented pipeline locations were confirmed, and no magnetic anomalies were identified that indicated potential locations of undocumented pipelines. Geophysical data indicate potential sandy bottom conditions at the proximal near shore areas, while soft, fine-grained sediment or shell/oyster mound are present at the water bottom in other locations. Geophysical data also allowed tentative identification of the Recent—Pleistocene contact and trend of the Goose Creek fault, consistent with the findings of previous studies. A number of shallow reflectors were also detected that probably are produced by buried and partially buried oyster mounds within the Recent sediments. Dredge material volumes should be dominated by a mixture of fine-grained materials in the silt and clay range, with substantial shell content at active and buried oyster mound locations.
